

# Chapter 1

## Stochastic Mean Field Particle Systems

From now on let the underlying probability space be given by  $(\Omega, \mathcal{F}, \mathbb{P})$ .

### 1.1 Basics of probability

**Definition 1.1.1 (Brownian Motion).** Real valued stochastic process  $W(\cdot)$  is called a Brownian motion (Wiener process) if

1.  $W(0) = 0$  a.s.
2.  $W(t) - W(s) \sim \mathcal{N}(0, t - s)$ , for all  $t, s \geq 0$
3.  $\forall 0 < t_1 < t_2 < \dots < t_n$ ,  $W(t_1), W(t_2) - W(t_1), \dots, W(t_n) - W(t_{n-1})$  are independent
4.  $W(t)$  is continuous a.s (sample paths)

**Remark (Properties).**

1.  $\mathbb{E}[W(t)] = 0$ ,  $\mathbb{E}[W(t)^2] = t$ , for all  $t > 0$
2.  $\mathbb{E}[W(t)W(s)] = t \wedge s$  a.s
3.  $W(t) \in \mathcal{C}^\gamma[0, T]$ ,  $\forall 0 < \gamma < \frac{1}{2}$ .
4.  $W(t)$  is nowhere differentiable a.s

additionally Brownian motions are martingales and satisfy the Markov property

**Definition 1.1.2 (Progressively measurable).** In addition to adaptation of a Stochastic process  $X_t$  we say it is progressively measurable w.r.t  $\mathcal{F}_t$  if  $X(s, \omega) : [0, t] \times \Omega \rightarrow \mathbb{R}$  is  $\mathcal{B}[0, t] \times \mathcal{F}_t$  measurable, i.e the  $t$  is included

**Definition 1.1.3 (Simple functions).** Instead of  $\mathcal{H}^2$  she uses  $\mathbb{L}^2(0, T)$  is the space of all real-valued progressively measurable processes  $G(\cdot)$  s.t

$$\mathbb{E}[\int_0^T G^2 dt] < \infty.$$

define  $\mathbb{L}$  analog

**Definition 1.1.4 (Step Process).**  $G \in \mathbb{L}^2(0, T)$  is called a step process when Partition of  $[0, T]$  exists s.t  $G(t) = G_k$  for all  $t_k \leq t \leq t_{k+1}$ ,  $k = 0, \dots, m-1$  note  $G_k$  is  $\mathcal{F}_{t_k}$  measurable R.V.

For step process we define the ito integral as a simple sum

**Definition 1.1.5 (Ito integral for step process).** Let  $G \in \mathbb{L}^2(0, T)$  be a step process is given by

$$\int_0^T G(t) dW_t = \sum_{k=0}^{m-1} G_k (W(t_{k+1}) - W(t_k)).$$

We take the left value of the process such that we converge against the right integral later

**Remark.** For two step processes  $G, H \in \mathbb{L}^2(0, T)$  for all  $a, b \in \mathbb{R}$ , we have linearity (note they may have two different partitions, so we need to make a bigger (finer) one to include both,)

1.  $\int_0^T (aG + bH) dW_t = a \int G + b \int H$
2.  $\mathbb{E}[\int_0^T G dW_t] = 0$  , because the Brownian motion has EV of 0
3.  $\mathbb{E}[(\int_0^T G dW_t)^2] = \mathbb{E}[\int_0^T G^2 dt]$  Ito isometry

**Proof.** First property is just defining a new partition that includes both process. Second property, the Idea of the proof is that

$$\begin{aligned} \mathbb{E}[\int_0^t G dW_t] &= \mathbb{E}[\sum_{k=0}^{m-1} G_k (W_{t_{k+1}} - W_{t_k})] \\ &= \sum_{k=0}^{m-1} \mathbb{E}[G_k (W(t_{k+1}) - W(t_k))] \end{aligned}$$

Remember  $G_k \sim \mathcal{F}_{t_k}$  m.b. and  $W(t_{k+1}) - W(t_k)$  is mb. wrt to  $\mathcal{F}_{t_k}$  future sigma algebra and it is independent of  $\mathcal{F}_{t_k}$  s.t the expectation de-

composes

$$\sum_{k=0}^{m-1} \mathbb{E}[G_k(W(t_{k+1}) - W(t_k))] = \sum_{k=0}^{m-1} \mathbb{E}[G_k] \mathbb{E}[W(t_{k+1}) - W(t_k)] = C \cdot 0 = 0.$$

For the variance decompose into square and non square terms , the non square terms dissappear by property 2 the rest follows by the variance of Brownian motion, be careful of which terms are actually independent , at leas one will always be independent of the other 3  $\square$

**Definition 1.1.6 (Ito Formula).** If  $u \in \mathcal{C}^{2,1}(\mathbb{R} \times [0, T]; R)$  then

$$\begin{aligned} du(x(t), t) &= \frac{\partial u}{\partial t}(x(t), t)dt + \frac{\partial u}{\partial x}(x(t), t)dx + \frac{1}{2} \frac{\partial^2 u}{\partial x^2} G^2 dt \\ &= \frac{\partial u}{\partial x}(x(t), t)GdW_t + \left( \frac{\partial u}{\partial t}(x(t), t) + \frac{\partial u}{\partial x}(x(t), t)F + \frac{1}{2} \frac{\partial^2 u}{\partial x^2} G^2 \right) dt. \end{aligned}$$

For  $dX = Fdt + GdW_t$  for  $F \in L^1([0, T])$  ,  $G \in L^2([0, T])$

**Proof.** The proof is split into the steps

1.

$$\begin{aligned} d(W_t^2) &= 2W_t dW_t + dt \\ d(tW_t) &= W_t dt + t dW_t. \end{aligned}$$

2.

$$\begin{aligned} dX_i &= F_i dt + G_i dW_t \\ d(X_1, X_2) &= X_2 dX_1 + X_1 dX_2 + G_1 G_2 dt \end{aligned}$$

3.

$$u(x) = x^m \quad m \geq 2.$$

4. Itos formula for  $u(x, t) = f(x)g(t)$  where  $f$  is a polynomial

I.e we prove the Ito formula for functions of the form  $u(x) = x^m$  and then Step 1 :

1.  $d(W_t^2) = 2W_t dW_t + dt$  which is equivalent to  $W^2(t) = W_0^2 + \int_0^t 2W_s dW_s + \int_0^t ds$
2.  $d(tW_t) = W_t dt + t dW_t$  which is equivalent to  $tW(t) - sW(0) = \int_0^t W_s ds + \int_0^t s dW_s$

Actually  $\forall$  a.e  $\omega \in \Omega$  :

$$2 \int_0^t W_s dW_s = 2 \lim_{n \rightarrow \infty} .$$

Now we prove (2)  $tW_t - 0W_0 = \int_0^t W_s ds + \int_0^t s dW_s$

$$\int_0^t s dW_s + \int_0^t W_s ds = \lim_{n \rightarrow \infty} \sum_{k=0}^{n-1} t_k^n (W(t_{k+1}^n) - W(t_k^n)) + \sum_{k=0}^{n-1} W(t_{k+1}^n) (t_{k+1}^n - t_k^n).$$

We choose the right value for the second integral

$$= \lim_{n \rightarrow \infty} \sum_{k=0}^{n-1} (-t_k^n W(t_k^n) + t_{k+1}^n W(t_{k+1}^n)) = W(t)t - W(0) \cdot 0.$$

Its product rule

$$\begin{aligned} dX_1 &= F_1 dt + G_1 dW_t \\ dX_2 &= F_2 dt + G_2 dW_t. \end{aligned}$$

This can be written as

$$d(X_1, X_2) = X_2 dX_1 + X_1 dX_2.$$

this shorthand notation actually means

$$\begin{aligned} X_1(t)X_2(t) - X_1(0)X_2(0) &= \int_0^t X_2 F_1 ds + \int_0^t X_2 G_1 dW_s \\ &\quad + \int_0^t X_1 F_2 ds + \int_0^t X_1 G_2 dW_s \\ &\quad + \int_0^t G_1 G_2. \end{aligned}$$

We prove for  $F_1, F_2, G_1, G_2$  are time independent

$$\begin{aligned}
 & \int_0^t (X_2 dX_1 + X_1 dX_2 + G_1 G_2 ds) \\
 &= \int_0^t (X_2 F_1 + X_1 F_2 + G_1 G_2) ds + \int_0^t (X_2 G_1 + X_1 G_2) dW_s \\
 &= \int_0^t (\underbrace{F_2 F_1 s + F_1 G_2 W_s}_{=X_2} + \underbrace{F_1 F_2 s + F_2 G_1 W_s}_{=X_1} + G_1 G_2) ds \\
 &+ \int_0^t (F_2 G_1 s + G_2 G_1 W_s + F_1 G_2 s + G_1 G_2 W_s) dW_s \\
 &= G_1 G_2 t + F_1 F_2 t^2 + (F_1 G_2 + F_2 G_1) \left( \underbrace{\int_0^t W_s ds + \int_0^t s dW_s}_{tW_t} \right) + 2G_1 G_2 \underbrace{\int_0^t W_s dW_s}_{W_t^2 - t} \\
 &= G_1 G_2 t + F_1 F_2 t^2 + (F_1 G_2 + F_2 G_1) t W_t + G_1 G_2 W_t^2 - G_1 G_2 t \\
 &= X_1(t) \cdot X_2(t).
 \end{aligned}$$

Where  $X_2(t) = \int_0^t F_2 ds + \int_0^t G_2 dW_s \stackrel{\text{cons.}}{=} F_2 t + G_2 W_t$

Extend the above idea by considering step processes  $(F_1, F_2, G_1, G_2)$  instead of time independent. Step processes are constant (related to time) and we can use the above prove for every time step  $t$  and just consider a summation over it.

For general  $F_1, F_2 \in L^1(0, T), G_1, G_2 \in L^2(0, T)$  then we take step processes to approximate them

$$\begin{aligned}
 \mathbb{E} \left[ \int_0^T |F_i^n - F_i| dt \right] &\rightarrow 0 \\
 \mathbb{E} \left[ \int_0^T |G_i^n - G_i|^2 dt \right] &\rightarrow 0
 \end{aligned}$$

$$X_i(t)^n = X_i(0) + \int_0^t F_i^n ds + \int_0^t G_i^n dW_s.$$

It holds

$$\begin{aligned}
 X_1^n(t) X_2(t)^n - X_1(0) X_2(0) &= \int_0^t X_2(s)^n F_1^n(s) ds + \int_0^t X_2(s) G_1(s)^n dW_s \\
 &+ \int_0^t X_1^n(s) F_2^n(s) ds + \int_0^t X_1(s)^n G_2^n(s) dW_s + \int_0^t G_1(s)^n G_2^n(s) ds.
 \end{aligned}$$

Only thing left is a convergence result (i.e DCT) since the processes are bounded or smth like that.

Step 3 if  $u(x) = x^m$ ,  $\forall m = 0, \dots$  to prove

$$d(X^m) = mX^{m-1}dX + \frac{1}{2}m(m-1)X^{m-2}G^2dt.$$

For  $m = 2$  the result is obtained by the product rule, By induction we prove for arbitrary  $m$

(IV) Suppose the statement hold for  $m - 1$

(IS)  $m - 1 \rightarrow m$

$$\begin{aligned} d(X^m) &= d(X \cdot X^{m-1}) = XdX^{m-1} + X^{m-1}dx + (m-1)X^{m-2}G^2dt \\ &\stackrel{\text{IS}}{=} X(m-1)X^{m-2}dx + X \cdot \frac{1}{2}(m-1)(m-2)X^{m-3}G^2dt + X^{m-1}dx + (m-1)X^{m-2}G^2dt \\ &= mX^{m-1}dx + (m-1)\left(\frac{m}{2} - 1 + 1\right)X^{m-2}G^2dt \\ &= \underbrace{mX^{m-1}}_{\partial_x u}dx + \frac{1}{2}\underbrace{m(m-1)X^{m-2}}_{\partial_x^2 u}G^2dt. \end{aligned}$$

Now  $u(x) = x^m$

$$dX = Fdt + GdW_t.$$

Step 4 If  $u(x, t) = f(x)g(t)$  where  $f$  is a polynomial

$$\begin{aligned} d(u(x, t)) &= d(f(x)g(t)) = f(x)dg + gdf(x) + G \cdot 0dt \\ &\stackrel{\text{S3}}{=} f(x)g'(t)dt + gf'(x)dx + \frac{1}{2}gf''(x)G^2dt. \end{aligned}$$

Itos formula is true for  $f(x)g(t)$ , it should thus also be true for functions  $u(x, t) = \sum_{i=1}^m g^i(t)f^i(x)$

Step 5: if  $u \in \mathcal{C}^{2,1}$  then we know there exists a sequence of polynomials  $f^i(x)$  s.t

$$u_n(x, t) = \sum_{i=1}^n f^i(x)g^i(t).$$

Then  $u_n \rightarrow u$  uniformly for any compact set  $K \subset \mathbb{R} \times [0, T]$ , we can thus apply Itos formula for each of the  $u_n$  and take the limit term wise  $\square$

**Remark.** One can get the existence of the polynomial sequence by using Hermetian polynomials

$$H_n(x) = (-1)^n e^{\frac{x^2}{2}} \frac{d^n}{dx^n} e^{-\frac{x^2}{2}}.$$

**Exercise.** If  $u \in \mathcal{C}^\infty$ ,  $\frac{\partial u}{\partial x} \in \mathcal{C}_b$  then prove Step 4  $\Rightarrow$  Step 5

Use Taylor expansion and use the uniform convergence of the Taylor series on any compact support

**Remark (Multi Dimensional Brownian Motion).** Multi dimensional Brownian motion

$$W(t) = (W^1(t), \dots, W^m(t)) \in \mathbb{R}^m$$

In each direction we should have a 1 dimensional Brownian motion and any two directions should be independent. We use the natural filtration  $\mathcal{F}_t = \sigma(W(s); 0 \leq s \leq t)$

**Definition 1.1.7 (Multi-Dimensional Ito's Integral).** We define the  $n$  dimensional integral for  $G \in L^2_{n \times m}([0, T])$ ,  $G_{ij} \in L^2([0, T])$   $1 \leq i \leq n$ ,  $1 \leq j \leq m$

$$\int_0^T G dW_t = \left( \int_0^T G_{ij} dW_t^j \right)_{n \times 1}.$$

With the Properties

$$\mathbb{E} \left[ \int_0^T G dW_t \right] = 0$$

$$\mathbb{E} \left[ \left( \int_0^T G dW_t \right)^2 \right] = \mathbb{E} \left[ \int_0^T |G|^2 dt \right].$$

Where  $|G|^2 = \sum_{i,j}^{n,m} |G_{ij}|^2$

**Definition 1.1.8 (Multi-Dimensional Ito process).** We define the  $n$  dimensional Ito process as

$$X(t) = X(s) + \int_s^t F_{n \times 1}(r) dr + \int_0^t G_{n \times m}(r) dW_{m \times 1}(r)$$

$$dX^i = F^i dt + \sum_{j=1}^m G^{ij} dW_t^j \quad 1 \leq i \leq n.$$

**Theorem 1.1.1 (Multi Dimensional Ito's formula).** We define the  $n$  dimensional Ito's formula as  $u \in C^{2,1}(\mathbb{R}^n \times [0, T], \mathbb{R})$

$$du(x(t), t) = \frac{\partial u}{\partial t}(x(t), t) dt + \nabla u(x(t), t) \cdot dx(t)$$

$$+ \frac{1}{2} \sum \frac{\partial^2 u}{\partial x_i \partial x_j}(x(t), t) \sum_{l=1}^m G^{il} G^{jl} dt.$$

**Proposition 1.1.1.** For real valued processes  $X_1, X_2$

$$\begin{cases} dX_1 = F_1 dt + G_1 dW_1 \\ dX_2 = F_2 dt + G_2 dW_2 \end{cases} \Rightarrow d(X_1, X_2) = X dX_2 + X_2 dX_1 + \sum_{k=1}^m G_1^k G_2^k dt.$$

Working with SDEs relies on a lot of notational rules as seen in the differential notation is just shorthand for the Integral form

**Definition 1.1.9.** Formal multiplication rules for SDEs

$$(dt)^2 = 0, \quad dt dW^k = 0, \quad dW^k dW^l = \delta_{kl} dt.$$

Using this notation we can simply itos formula as follows

$$\begin{aligned} du(X, t) &= \frac{\partial u}{\partial t} dt + \nabla_x u \cdot dX + \frac{1}{2} \sum_{i,j=1}^n \frac{\partial^2 u}{\partial x_i \partial x_j} dX^i dX^j \\ &= \frac{\partial u}{\partial t} dt + \sum_{i=1}^n \frac{\partial u}{\partial X^i} F^i dt + \sum_{i=1}^n \frac{\partial u}{\partial X^i} \sum_{k=1}^m G^{ik} dW_k \\ &\quad + \frac{1}{2} \sum_{i,j=1}^n \frac{\partial^2 u}{\partial x_i \partial x_j} \left( F^i dt + \sum_{k=1}^m G^{ik} dW_k \right) \left( F^j dt + \sum_{l=1}^m G^{jl} dW_l \right) \\ &= \left( \frac{\partial u}{\partial t} + F \cdot \nabla u + \frac{1}{2} H \cdot D^2 u \right) dt + \sum_{i=1}^n \frac{\partial u}{\partial x_i} \sum_{k=1}^m G^{ik} dW_k. \end{aligned}$$

Where

$$\begin{aligned} dX^i &= F^i dt + \sum_{k=1}^m G^{ik} dW_k \\ H_{ij} &= \sum_{k=1}^m G^{ik} G^{jk}, \quad A \cdot B = \sum_{i,j=1}^m A_{ij} B_{ij}. \end{aligned}$$

Typical example

$$G^T G = \sigma I_{n \times n}.$$

**Example.** If  $F$  and  $G$  are deterministic

$$dX_{n \times 1} F(t)_{n \times 1} dt + G_{n \times m} dW_t m \times 1.$$

Then for arbitrary test function  $u \in \mathcal{C}_0^\infty(\mathbb{R}^n)$  then by Ito's formula

$$\begin{aligned} u(x(t)) - u(x(0)) &= \int_0^t \nabla u(x(s)) \cdot F(s) ds + \int_0^t \frac{1}{2} (G^T G) : D^2 u(x(s)) ds \\ &\quad + \int_0^t \nabla u(x(s)) \cdot G(s) dW_s. \end{aligned}$$

Let  $\mu(s, \cdot)$  be the law of  $X(s)$  then we take the expectation of the above integral

$$\begin{aligned} \int_{\mathbb{R}^n} u(x) d\mu(s, x) - \int_{\mathbb{R}^n} u(x) d\mu_0(x) &= \int_0^t \int_{\mathbb{R}^n} \nabla u(x) \cdot F(s) d\mu(s, x) \\ &+ \int_0^t \int_{\mathbb{R}^n} \frac{1}{2} (G^T(s) G(s)) : D^2 u(x) \cdot d\mu(s, x) + 0. \end{aligned}$$

**Definition 1.1.10** (Parabolic Operator).

$$\partial_t u - \frac{1}{2} \sum_{i,j=1}^n D_{ij} \left( \sum_{k=1}^m G^{ik} G^{kj} \right) \mu + \nabla \cdot (F\mu) = 0.$$

**Example.** If  $F = 0$   $m = n$  and  $G = \sqrt{2}I_{n \times n}$  then

$$dX = \sqrt{2} dW_t.$$

And the law of  $X$ ,  $\mu$  fulfills the heat equation

$$\mu_t = \Delta \mu = 0.$$

How does this all translate to our Mean field Limit, consider a particle system given by

$$\begin{cases} dX_N &= F(X_N)dt + \sqrt{2}dW_{dN \times 1} \\ dx_i &= \frac{1}{N} \sum K(x_i, x_j)dt + \sqrt{2}dW_t^1 \\ x_i(0) &= x_{0,i} \\ \mu_N(t) &= \frac{1}{N} \sum_{i=1}^N \delta_{x_i(t)} \end{cases} \quad 1 \leq i \leq N \quad N \rightarrow \infty.$$

At time  $t = 0$  the  $x_i$  are independent random variables at any time  $t > 0$  they are dependent and the particles have joint law

$$(x_1(t), \dots, x_N(t)) \sim u(x_1, \dots, x_N).$$

Where  $u \in \mu(\mathbb{R}^{dN})$  by Ito's formula we get for arbitrary test function  $\forall \varphi \in \mathcal{C}_0^\infty(\mathbb{R}^{dN})$

$$\begin{aligned} \varphi(X_N) &= \varphi(X_N(0)) + \int_0^t \nabla_{dN} \varphi \cdot \begin{pmatrix} \vdots \\ \frac{1}{n} \sum_{j=1}^N K(x_i, x_j) \\ \vdots \end{pmatrix} X_N \\ &+ \int_0^t \Delta_{X_N} \varphi dt + \int_0^t \sqrt{2} \nabla \varphi dW_t^i. \end{aligned}$$

Taking the expectation on both sides, then the last term disappears by definition of Ito processes

$$\partial_t - \sum_{i=1}^N \Delta_i u + \sum_{i=1}^N \nabla_{x_i} \left( \frac{1}{N} \sum_{j=1}^N K(x_i, x_j) u \right) = 0.$$

Now consider the Mean-Field-Limit, if the joint particle law can be rewritten as the tensor product of a single  $\bar{u}$

$$u(x_1, \dots, x_N) = \bar{u}^{\otimes N}.$$

the equation simplifies

$$\partial_t - \sum_{i=1}^N \Delta_i u + \sum_{i=1}^N \nabla_{x_i} (\bar{u}^{\otimes N} k \star \bar{u}(x_i)) = 0.$$

## 1.2 Solving Stochastic Differential Equations

The setup of the following section will be the following

**Definition 1.2.1 (Basic Setup).** We consider the probability space  $(\Omega, \mathcal{F}, \mathbb{P})$ , With a  $m - D$  dimensional Brownian motion  $W(\cdot)$ . Let  $X_0$  be an  $n - D$  dimensional random variable independent of  $W(0)$ , then our Filtration is given by

$$\mathcal{F}_t = \sigma(X_0) \cup \sigma(W(s), 0 \leq s \leq t).$$

Note for better understanding the dimensions will be included in the following definition, but we generally leave them out.

**Definition 1.2.2 (SDE).** Given the above basic setup we are trying to solve equations of the type

$$\begin{cases} d \underbrace{X_t}_{n \times 1} &= \underbrace{b(X_t, t)}_{n \times 1} dt + \underbrace{B(X_t, t)}_{n \times m} d \underbrace{W_t}_{m \times 1} & 0 \leq t \leq T \\ X_t|_{t=0} &= X_0 & X : (t, \omega) \rightarrow \mathbb{R}^n \end{cases}.$$

Where

$$\begin{aligned} b : (x, t) \in \mathbb{R}^n \times [0, T] &\rightarrow \mathbb{R}^n \\ B : (x, t) \in \mathbb{R}^n \times [0, T] &\rightarrow M^{n \times m}. \end{aligned}$$

**Remark.** The differential equation should always be understood as the Integral equation

$$X_t - X_0 = \int_0^t b(X_s, s) ds + \int_0^t B(X_s, s) dW_s.$$

**Definition 1.2.3 (Solution).** We say an  $\mathbb{R}^n$ -valued stochastic process  $X(\cdot)$  is a solution of the SDE if

1.  $X_t$  is progressively measurable w.r.t  $\mathcal{F}_t$
2. (drift)  $F := b(X_t, t) \in L_n^1([0, T]) \Leftrightarrow \int_0^t \mathbb{E}[F_s] ds < \infty$

3. (diffusion)  $G := B(X_t, t) \in L^2_{n \times m}([0, T]) \Leftrightarrow \int_0^t \mathbb{E}[|G_s|^2] ds < \infty$

Reminder that (1) implies that for any given  $t \in [0, T]$   $X_t$  is random variable measurable with respect to  $\mathcal{F}_t$

The goal from now on is to prove the existence and uniqueness of such solutions, we formulate the following theorem, one should remember that if the diffusion term  $B(X_t, t)$  is 0 then we get a unique solution iff  $b(X_t, t)$  is Lipschitz

**Theorem 1.2.1 (Existence and Solution).** Suppose  $b : \mathbb{R}^n \times [0, T] \rightarrow \mathbb{R}^n$  and  $B : \mathbb{R}^n \times [0, T] \rightarrow M^{n \times m}$ , then we get the necessary condition that they are continuous and (globally) Lipschitz continuous with respect to  $x$  i.e  $\exists L > 0$  such that for arbitrary  $\forall x, \tilde{x} \in \mathbb{R}^n$  and  $t \in [0, T]$  it holds

$$|b(x, t) - b(\tilde{x}, t)| + |B(x, t) - B(\tilde{x}, t)| \leq L|x - \tilde{x}|.$$

and the linear growth condition

$$|b(x, t)| + |B(x, t)| \leq L(1 + |x|).$$

The initial data  $X_0$  should be square integrable  $x_0 \in L^2_n(\Omega)$  and that  $X_0$  is independent of  $W^t(0)$

Whenever the above conditions hold then there exists a unique solution  $X \in L^2_n([0, T])$  of the SDE.

**Proof.** We begin by proving the uniqueness of solution.

Suppose we have two solutions  $X$  and  $\tilde{X}$  to the SDE then we need to show that they are indistinguishable, then by using the definition of a solution

$$X_t - \tilde{X}_t = \int_0^t (b(X_s, s) - b(\tilde{X}_s, s)) ds + \int_0^t B(X_s, s) - B(\tilde{X}(s), s) dW_s.$$

If the diffusion term were to be 0 we could use a Grönwall type inequality and get the uniqueness. To work with the diffusion term we consider the square of the above and apply Itos isometry. Note that generally  $|a + b|^2 \not\leq (a^2 + b^2)$  which is why we need the extra 2.

$$|X_t - \tilde{X}_t|^2 \leq 2 \left| \int_0^t (b(X_s, s) - b(\tilde{X}_s, s)) ds \right|^2 + \left| \int_0^t B(X_s, s) - B(\tilde{X}(s), s) dW_s \right|^2.$$

Now consider the following

$$\begin{aligned}
 \mathbb{E}[|X_t - \tilde{X}_t|^2] &\leq 2\mathbb{E}\left[\left|\int_0^t |b(X_s, s) - b(\tilde{X}_s, s)|^2 ds\right|\right] \\
 &\quad + 2\mathbb{E}\left[\left|\int_0^t B(X_s, s) - B(\tilde{X}_s, s) dW_s\right|^2\right] \\
 &\stackrel{\text{Höld.}}{\leq} 2t\mathbb{E}\left[\int_0^t |b(X_s, s) - b(\tilde{X}_s, s)|^2 ds\right] + 2\mathbb{E}\left[\int_0^t |B(X_s, s) - B(\tilde{X}_s, s)|^2 ds\right] \\
 &\stackrel{\text{Lip.}}{\leq} 2(t+1)L^2 \mathbb{E}\left[\int_0^t |X_s - \tilde{X}_s|^2 ds\right] \\
 &= 2(t+1)L^2 \int_0^t \mathbb{E}[|X_s - \tilde{X}_s|^2] ds
 \end{aligned}$$

Where the following Hölders inequality was used

$$\begin{aligned}
 \left(\int_0^t 1|f| ds\right)^2 &\leq \left(\int_0^t 1^2 ds\right)^{\frac{1}{2} \cdot 2} \cdot \left(\int_0^t |f|^2 ds\right)^{\frac{1}{2} \cdot 2} \\
 &\leq t \int_0^t |f|^2 ds.
 \end{aligned}$$

Now by Gronwall's inequality we have

$$\mathbb{E}[|X_t - \tilde{X}_t|^2] = 0.$$

i.e  $X_t$  and  $\tilde{X}_t$  are modifications of each other and it remains to show that they are actually indistinguishable.

Define

$$A_t = \{\omega \in \Omega \mid |X_t - \tilde{X}_t| > 0\} \quad \mathbb{P}(A_t) = 0.$$

$$\mathbb{P}\left(\max_{t \in \mathbb{Q} \cap [0, T]} |X_t - \tilde{X}_t| > 0\right) = \mathbb{P}\left(\bigcup_{k=1}^{\infty} A_{t_k}\right) = 0.$$

Now since  $X_t(\omega)$  is continuous in  $t$  we can extend the maximum over the entire interval  $[0, T]$

$$\max_{t \in \mathbb{Q} \cap [0, T]} |X_t - \tilde{X}_t| = \max_{t \in [0, T]} |X_t - \tilde{X}_t|.$$

Then the probability over the entire interval must also be 0

$$\mathbb{P}\left(\max_{t \in [0, T]} |X_t - \tilde{X}_t| > 0\right) = 0 \quad \text{i.e. } X_t = \tilde{X}_t \quad \forall t \text{ a.s..}$$

This concludes the uniqueness proof, for existence as in the deterministic case we use Picard iteration.

Define the Picard iteration by

$$\begin{aligned} X_t^0 &= X_0 \\ &\vdots \\ X_t^{n+1} &= X_0 + \int_0^t b(X_s^n, s) ds + \int_0^t B(X_s^n, s) dW_s. \end{aligned}$$

Let  $d(t)^n = \mathbb{E}[|X_t^{n+1} - X_t^n|^2]$  we claim that by induction  $d^n(t) \leq \frac{(Mt)^{n+1}}{(n+1)!}$  for some  $M > 0$ .

**IA:** For  $n = 0$  we have

$$\begin{aligned} d(t)^0 &= \mathbb{E}[|X_t^1 - X_t^0|^2] \leq \mathbb{E}[2(\int_0^t b(X_0, s) ds)^2 + 2(\int_0^t B(X_0, s) dW_s)^2] \\ &\leq 2t\mathbb{E}[\int_0^t L^2(1 + X_0^2) ds] + 2\mathbb{E}[\int_0^t L^2(1 + X_0) ds] \\ &\leq tM \quad \text{where } M \geq 2L^2(1 + \mathbb{E}[X_0^2]) + 2L^2(1 + T). \end{aligned}$$

**IV:** suppose the assumption holds for  $n - 1 \in \mathbb{N}$

**IS:** Take  $n - 1 \rightarrow n$  then

$$\begin{aligned} d^n(t) &= \mathbb{E}[|X_t^{n+1} - X_t^n|^2] \leq 2L^2T\mathbb{E}[\int_0^t |X_s^n - X_s^{n-1}|^2 ds] + 2L^2\mathbb{E}[\int_0^t |X_s^n - X_s^{n-1}|^2 ds] \\ &\stackrel{\text{IV}}{\leq} 2L^2(1 + T) \int_0^t \frac{(Ms)^n}{n!} ds \\ &= 2L^2(1 + t) \frac{M^n}{(n+1)!} t^{n+1} \leq \frac{M^{n+1}t^{n+1}}{(n+1)!}. \end{aligned}$$

Issue now is that because of  $\Omega$  we cannot use completeness to argue the convergence, instead we use a similar argument to the uniqueness proof.

$$\begin{aligned} &\mathbb{E}[\max_{0 \leq t \leq T} |X_t^{n+1} - X_t^n|^2] \\ &\leq \mathbb{E}[\max_{0 \leq t \leq T} 2 \left| \int_0^t b(X_s^n, s) - b(X_s^{n-1}, s) ds \right|^2 + 2 \left| \int_0^t B(X_s^n, s) - B(X_s^{n-1}, s) dW_s \right|^2] \\ &\leq 2TL^2\mathbb{E}[\int_0^T |X_s^n - X_s^{n-1}|^2 ds] + 2\mathbb{E}[\max_{0 \leq t \leq T} \left| \int_0^t B(X_s^n, s) - B(X_s^{n-1}, s) ds dW_s \right|] \\ &\leq 2TL^2\mathbb{E}[\int_0^T |X_s^n - X_s^{n-1}|^2 ds] + 8\mathbb{E}[\int_0^T |B(X_s^n, s) - B(X_s^{n-1}, s)|^2 ds] \\ &\leq C \cdot \mathbb{E}[\int_0^T |X_s^n - X_s^{n-1}|^2 ds]. \end{aligned}$$

Where we used the following Doob's martingales Lp inequality

$$\mathbb{E}[\max_{0 \leq s \leq t} |X(s)|^p] \leq \left(\frac{p}{p-1}\right)^p \mathbb{E}[|X(t)|^p].$$

By Picard iteration we know the distance  $d^n(t) = \mathbb{E}[|X_s^n - X_s^{n-1}|^2]$  is bounded by

$$\begin{aligned} C \cdot \mathbb{E}\left[\int_0^T |X_s^n - X_s^{n-1}|^2 ds\right] &= C \cdot \int_0^T \mathbb{E}[|X_s^n - X_s^{n-1}|^2] ds \\ &\leq \int_0^T \frac{(Mt)^n}{(n)!} \\ &= C \frac{M^n T^{n+1}}{(n+1)!}. \end{aligned}$$

Further more we get with a Markovs inequality

$$\begin{aligned} \mathbb{P}\left(\underbrace{\max_{0 \leq t \leq T} |X_t^{n+1} - X_t^n|^2}_{A_n} > \frac{1}{2^n}\right) &\leq 2^{2n} \mathbb{E}\left[\max_{0 \leq t \leq T} |X_t^{n+1} - X_t^n|^2\right] \\ &\leq 2^{2n} \frac{CM^n T^{n+1}}{(n+1)!}. \end{aligned}$$

Then by Borel-Cantelli we know

$$\sum_{n=0}^{\infty} \mathbb{P}(A_n) \leq C \sum_{n=0}^{\infty} 2^{2n} \frac{(MT)^n}{(n+1)!} < \infty \Rightarrow \mathbb{P}\left(\bigcap_{n=0}^{\infty} \bigcup_{m=n}^{\infty} A_m\right) = 0.$$

Define by a telescope argument

$$X_t^n = X_t^0 + \sum_{j=1}^{n-1} (X_t^{j+1} - X_t^j).$$

Then the above converges to

$$X_t = X_0 + \int_0^t b(X_s, s) ds + \int_0^t B(X_s, s) dW_s.$$

□

**Remark.** Uniqueness in a stochastic sense means that for two solution  $X, \tilde{X}$  we have

$$\mathbb{P}(X(t) = \tilde{X}(t), \forall t \in [0, T]) = 1 \Leftrightarrow \max_{0 \leq t \leq T} |x(t) - \tilde{x}(t)| = 0 \text{ a.s..}$$

I.e they are indistinguishable

As a small side note we consider this example to distinguish modifications and indistinguishable.

**Example.** First note that for any  $t \in [0, T]$  we have the following inclusion

$$A := \{X(t) = \tilde{X}(t), \forall t \in [0, T]\} \subset \{X(t) = \tilde{X}(t)\} := A_t.$$

i.e

$$\mathbb{P}(A) \leq P(A_t).$$

Such that indistinguishability implies modification where modification means

$$\forall t \in [0, T] : \mathbb{P}(A_t) = 1.$$

## Chapter 2

# Appendix

**Theorem 2.0.1** (Divergence Theorem ). Let  $\Omega \subset \mathbb{R}^n$  be bounded and open with  $\partial\Omega$  being a  $(n-1)$ - dimensional sub-manifold of  $\mathbb{R}^n$ . Let  $F : \overline{\Omega} \rightarrow \mathbb{R}^n$  be continuous and differentiable on  $\Omega$  such that  $\nabla F$  continuously to  $\partial\Omega$ . Then we have :

$$\int_{\Omega} \nabla \cdot F d\mu = \int_{\partial\Omega} F \cdot N d\sigma.$$

where  $N$  is the outward pointing normal. (last component is positive)
